Supporting Information

ABSTRACT: A sustainable strategy by internally recycling an organocatalyst as a reactant in a downstream reaction to improve the atom efficiency of organocatalytic tandem reactions is described. Specifically, a one-pot tandem Cloke–Wilson/Boulton–Katritzky reaction of cyclopropylketones with a hydroxylamine has been developed for the synthesis of fully substituted isoxazoles, in which the hydroxylamine serves as both an upstream catalyst and a downstream reactant.

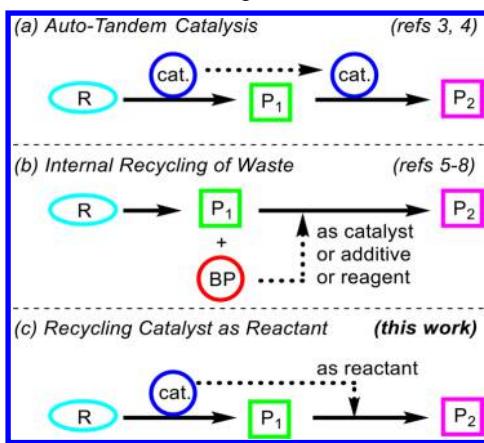

An important goal of synthetic chemistry is to develop green methods that maximize the atom and step economy of organic reactions and minimize the adverse environmental effects.¹ Toward this end, tandem reactions,² in which multiple reactions are combined into one operation, have been extensively investigated to enhance the efficiency of the chemical process. The convergent nature of tandem reactions also provides an opportunity for achieving the multifaceted use of the catalysts or reagents to further improve the atom efficiency of the process. For example, the “auto-tandem catalysis”³ involving a single catalyst to facilitate two or more distinct chemical transformations in a single flask has been applied in a large number of tandem reactions showing great synthetic utility (Scheme 1a).⁴ A sustainable strategy of “internal recycling of waste”⁵ has also been developed in which the byproduct of a stoichiometric reaction is recycled as a catalyst,⁶ additive,⁷ or reagent⁸ for the following steps (Scheme 1b). Particularly, Shibasaki,^{7f} Zhou,^{6d,g,7a,c} and Toy^{6h,j} have developed sustainable processes based on the Wittig reaction

by utilizing the phosphine oxide byproduct to promote an array of downstream transformations. Loh^{6o} and Alaimo⁶ⁿ have demonstrated that In⁰-mediated processes (e.g., Barbier reaction) could be integrated with reactions using an in situ generated In^{III} byproduct as a Lewis acid catalyst. Wu and co-workers^{6c,f,i,l} have reported the combination of I₂-mediated iodination of ketones with downstream reactions that were catalyzed by the thus-formed iodine species (e.g., HI, CuI). Recently, a sustainable Mo-catalyzed reduction/annulation process of nitrobenzenes with glycols has been demonstrated by Sanz and co-workers^{8a,d} for the synthesis of nitrogenated heterocycles, in which the reduction byproducts of glycols, i.e. aldehydes or ketones, are internally incorporated into the final product. Despite this progress, new strategies to improve the atom efficiency of tandem reactions are still of essential importance.

Organocatalysis⁹ has been established as a pivotal methodology due to its versatility and metal-free green nature. Various manifolds of organocatalysis such as nucleophilic catalysis,¹⁰ enamine catalysis,¹¹ iminium catalysis,¹² NHC catalysis,¹³ and Brønsted acid catalysis¹⁴ have flourished in recent decades. In spite of their efficiency,¹⁵ an arguable disadvantage of organocatalysis is the frequent requirement of a high catalyst loading (typically 20 mol %), which compromises the overall atom efficiency and limits its large-scale application in industry. Although several methods for addressing this issue have been attempted, such as recycling¹⁶ and immobilization¹⁷ of the catalyst, the fundamental inefficiency remains. As part of our interest in organocatalysis,¹⁸ we herein report a new sustainable strategy of “recycling the catalyst as the reactant” that internally reuses the organocatalyst as a reactant in a downstream reaction (Scheme 1c). The strategy has the potential to improve the atom efficiency of tandem processes,

Scheme 1. Sustainable Strategies for Tandem Reactions

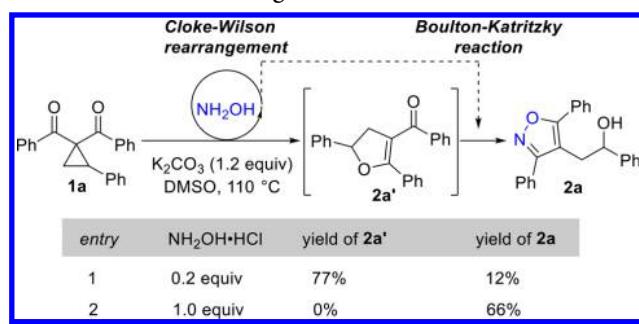

Received: September 11, 2018

Published: October 4, 2018

and also circumvents the concern of a large catalyst loading in organocatalysis since all catalyst material is incorporated into the final product. Furthermore, the capacity to use relatively simple and less reactive organocatalysts can be realized, since stoichiometric quantities of reagent compensate for reduced catalytic activity.

In light of our recent studies of organocatalytic ring-opening reactions of cyclopropanes,^{18a,b} we envisaged that simple and inexpensive hydroxylamine could not only catalyze the Cloke–Wilson rearrangement¹⁹ of cyclopropylketones, but also promote a subsequent Boulton–Kratzky reaction²⁰ of the resulting dihydrofurans to finally afford isoxazole products (**Scheme 2**). Gratifyingly, these two distinct transformations

Scheme 2. Initial Investigation

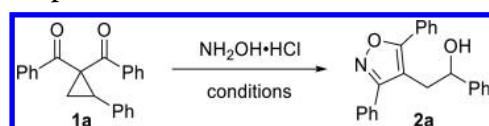

could be successfully converged into one pot. When cyclopropylketone **1a** was treated with a catalytic amount of hydroxylamine (20 mol %) at 110 °C in DMSO, the reaction produced the dihydrofuran **2a'** in 77% yield together with the desired isoxazole **2a** in 12% yield (**Scheme 2**, entry 1). Under identical conditions with a stoichiometric amount of hydroxylamine, the reaction produced **2a** in 66% yield as the sole product (**Scheme 2**, entry 2).²¹ Thus, the transformation involves a seamless integration of two reactions utilizing hydroxylamine as both catalyst and reactant, respectively, which presents a new sustainable strategy for tandem reactions.

On the basis of these encouraging results, the conditions of the Cloke–Wilson/Boulton–Kratzky reaction were optimized (**Table 1**). Among several common bases tested, K₂CO₃ still emerged as the best (entries 1–6). Solvent screening indicated that DMSO was crucial to the reaction, as THF, CH₂Cl₂, CH₃CN, CH₃OH, 1,4-dioxane, and DMF all provided very poor yields (entries 7–12). A survey of temperature found substantially lower yields at a reduced temperature of 90 or 70 °C and an improved yield of 72% at 130 °C (entries 13–15). When the amount of NH₂OH·HCl and K₂CO₃ was increased, the yield could be enhanced to 91% (entry 16). Finally, the yield of **2a** could be further improved to 93% when NH₂OH·HCl and K₂CO₃ were introduced in two time-separated additions (entry 17). Thus, the optimized condition consists of heating cyclopropylketones at 130 °C in DMSO with 2.0 equiv of NH₂OH·HCl and 2.4 equiv of K₂CO₃ added in two portions.

Utilizing these conditions, the scope of the tandem Cloke–Wilson/Boulton–Kratzky reaction was probed (**Scheme 3**). First, a range of cyclopropylketones bearing various aromatic substitutions (R¹, R² = aryl) proved to work well in the tandem reaction, giving the desired isoxazoles **2a–h** in good to excellent yields (65–97%). The product structure was unequivocally established by X-ray crystallography (for **2c**, CCDC: 1861088; **2f**, CCDC: 1861089; see Supporting

^aUnder N₂ and at indicated temperature, to a solution of **1a** (0.2 mmol) in the solvent (2.0 mL) were added the base and NH₂OH·HCl, and the mixture was stirred for 24 h. ^bIsolated yield. ^cK₂CO₃ and NH₂OH·HCl were added in two portions in 20% and 80%, respectively, over 24 h interval.

Information. Vinyl substituted cyclopropylketones (R¹ = vinyl) were also effective which produced the corresponding allylic alcohol products **2i–n** in 40–78% yields. Substrates containing aliphatic ketones (R² = Me) were well tolerated in these cases. In addition, alkyl substituted cyclopropylketones (R¹ = Me) were competent providing isoxazoles **2o–q** in good yields (56–78%) under our standard conditions. Furthermore, nonsubstituted cyclopropylketones (R¹ = H) also reacted smoothly to afford products **2r–t** bearing a primary alcohol in high yields (79–90%). Of note, cyclopropylketone **1u**, bearing two different ketone moieties, delivered a pair of regioisomeric isoxazoles **2u** and **2u'** in a 3:1 ratio and 55% combined yield. Taken together, the above results suggest a broad scope of the tandem Cloke–Wilson/Boulton–Kratzky reaction, which includes aryl-, alkyl-, vinyl-, and nonsubstituted cyclopropylketones featuring either aromatic or aliphatic ketones. To demonstrate the practicality, a scale-up reaction of **1a** (3.0 mmol) was conducted which afforded the product **2a** in 0.76 g, 78% yield.

Subsequently, we probed the possibility of using hydrazine as both a catalyst and reactant to mediate the Cloke–Wilson/Boulton–Kratzky reaction of cyclopropylketones to generate the corresponding pyrazoles. However, this attempt was not successful because hydrazine failed to catalyze the Cloke–Wilson rearrangement. Alternatively, when DABCO was employed as the organocatalyst, the desired pyrazoles **3** could be generated in one pot in excellent yields from representative cyclopropylketones **1** (**Scheme 4**). This result, however, corroborates the dual role of hydroxylamine as both catalyst and reactant in the Cloke–Wilson/Boulton–Kratzky reaction.

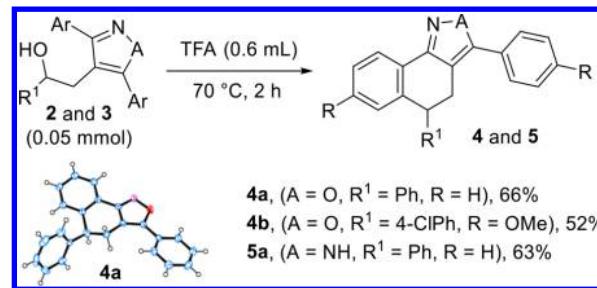

Scheme 3. Substrate Scope^aScheme 4. One-Pot Synthesis of Pyrazoles 3^a

^aConditions: DABCO (0.5 equiv), DMSO, 120 °C, 24 h, then NH₂NH₂·H₂O (2.0 equiv), K₂CO₃ (2.4 equiv), 24 h.

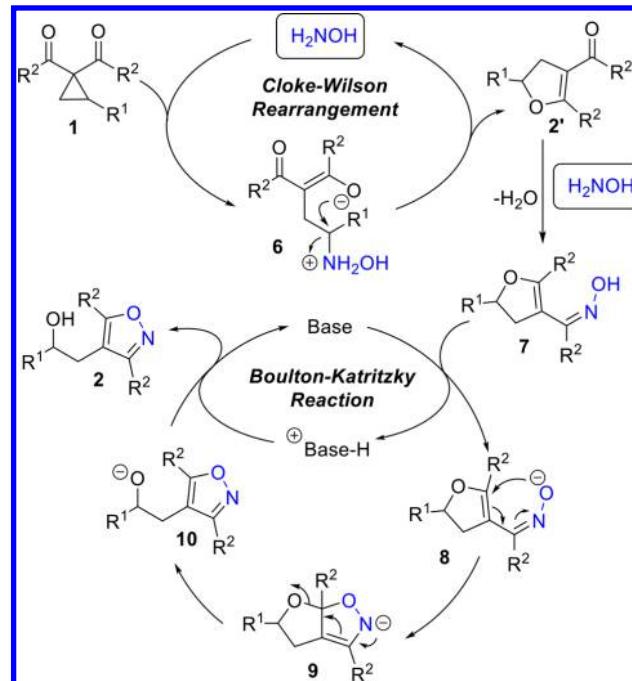

Isoxazoles²² and pyrazoles²³ are privileged heterocycles embedded in a large number of biologically active molecules and pharmaceuticals. The above Cloke–Wilson/Boulton–Katritzky reactions thus provide an efficient and convenient route to these heterocycles. The homobenzylic alcohol unit of the products offers a good opportunity for further elaboration. To demonstrate the potential, Friedel–Crafts alkylations of the products in the presence of TFA²⁴ were achieved to access tricyclic skeletons 4 and 5 in good yields (Scheme 5). The structure of 4a was confirmed by X-ray crystallography (CCDC: 1861090).

A plausible mechanism for the Cloke–Wilson/Boulton–Katritzky tandem reaction is proposed in Scheme 6. For the initial Cloke–Wilson rearrangement,^{18b} nucleophilic attack of

Scheme 5. Elaboration of Products for the Synthesis of Tricyclic Heterocycles

Scheme 6. Proposed Mechanism

NH₂OH on cyclopropane 1 via a homoconjugate addition pathway²⁵ produces an enolate intermediate 6. The anion then undergoes a favorable 5-exo-tet cyclization to give the dihydrofuran 2' and release the NH₂OH catalyst. The subsequent Boulton–Katritzky reaction initiates when NH₂OH acts as a reactant to condense with the dihydrofuran 2' to afford oxime 7, which is deprotonated by a catalytic amount of base (e.g., K₂CO₃) to give intermediate 8. Cyclization then occurs to generate 9, which undergoes fragmentation and protonation to afford the aromatic heterocycle 2. The isolation of intermediate 2a', as shown in Scheme 2, entry 1, suggests the rate of the Cloke–Wilson rearrangement should be significantly faster than the downstream Boulton–Katritzky reaction.

In summary, we have described a new sustainable strategy of “recycling catalyst as reactant” which holds great promise for improving the atom efficiency of organocatalytic tandem reactions. Specifically, a hydroxylamine-mediated Cloke–Wilson/Boulton–Katritzky reaction of cyclopropylketones has been developed for the efficient assembly of fully substituted isoxazoles, wherein the hydroxylamine serves as both the catalyst for the Cloke–Wilson rearrangement and a reactant for the downstream Boulton–Katritzky reaction. By recovering the catalyst as a reactant, the strategy may

circumvent the concern of a high catalyst loading of organocatalysis. In addition, utilizing stoichiometric amounts of catalyst allows the use of relatively simple and less reactive organocatalysts to promote the reaction. Efforts are underway in our laboratory to evaluate this strategy in other tandem organocatalytic reactions.
